Windows Event ID Cheat Sheet

Event ID	What it means	When to use it
4624	An account successfully logged on.	Confirm expected access; inspect account, source/workstation, logon type, and authentication details.
4625	An account failed to log on.	Investigate brute-force attempts, password spraying, mistyped credentials, or unexpected source hosts.
4634	An account logged off.	Correlate session end times with logon and activity records.
4648	A logon was attempted using explicit credentials.	Investigate RunAs, scheduled tasks, or unexpected use of alternate credentials.
4672	Special privileges assigned to a new logon.	Check whether an administrative or highly privileged account logged on as expected.
4688	A new process was created.	Hunt for suspicious executables, command lines (if auditing is configured), and parent/child process patterns.
4697	A service was installed in the system (Security log, when audited).	Investigate newly installed services that may provide persistence or remote execution.
4720	A user account was created.	Verify the creator, target account, timing, and business justification.
4722	A user account was enabled.	Check whether an account was enabled by an authorized administrator.
4724	An attempt was made to reset an account's password.	Investigate unexpected password resets, especially for privileged accounts.
4732	A member was added to a security-enabled local group.	For the Administrators group, validate who added which account and why.
4768	A Kerberos authentication ticket-granting ticket (TGT) was requested.	Review Kerberos authentication patterns and failures; event is typically logged on a domain controller.
4769	A Kerberos service ticket was requested.	Investigate unusual service-ticket requests and possible Kerberos abuse; correlate account, service, and source.
4776	A computer attempted to validate an account's credentials using NTLM.	Review NTLM authentication success/failure and the source workstation; typically logged on the validating computer/domain controller.
1102	The Windows Security audit log was cleared.	Treat unexpected clearing as high priority; identify the actor and correlate surrounding events and other log sources.

Useful triage workflow

- Start with the event timestamp, account, computer, and source address/workstation where available.
- Correlate 4624/4625 with logon type, authentication package, and nearby 4634 events.
- For account or privilege changes, correlate 4720, 4722, 4724, and 4732 with the initiating account and change window.
- For suspected persistence or execution, correlate 4697 and 4688 with service names, executable paths, command lines (if logged), and endpoint telemetry.
- Event 1102 means the Security audit log was cleared; confirm whether there was an approved administrative reason and check centralized logs.
